Flexybus is taxi sharing mobile application.

Technical architecture and functionalities:

Client

1. Mobile application will be available for IOS and Android systems. Hence mobile application will be built using cross-platform language Flutter. Every action of client and driver would be done in mobile application, while admin will control workflow and track actions of users in web version of application.
2. On mobile app client is able to order a cab, by selecting right pickup location (using map and entering location name), destination location (using map and entering location name), type of vehicle(class), date and time, pickup time, leave a comment if needed(not mandatory), select payment method (card or cash).
3. Pricing is done based on distance of ride. EX: for every km, for economy class 1 dollar is charged, for 10 km total price will be 10 dollars.
4. Clients register with their phone number and can attach their email during registration. During the registration the types of data which will be required from client: Full name, age, email, password for account.
5. Client will receive time sensitive notification from the app, during the ride and apart from it.
6. Account management of client. Client can change their data, password, add favourite location (saved) and manage them, phone number (verification important after every change through email/ phone number).

Driver

1. Driver registers with their full name, own photo(only face), phone number (verification mandatory), car model, car number, driver license, email, password.
2. Account management of driver. As user every data can be contolled in settings. Every detail can be changed with a requirement of verification.
3. Payment method. Payment can be done with two ways, by calculating total price of ride, client will pay by cash or card, if it's done by card, money will be transferred to virtual wallet where he can withdraw money to his card. Amount of money he has in his account will be visible in application too.

4. Order selection and acception. Orders will be sent to nearest drivers where they have to accept the order from client in certain timeline(ex: in 1 minute), every driver will be notified about the order so they wont miss any. If any drivers from nearby didnt accept the order, it appears on screen to those who are a bit further from the location.
5. Order tracking. Every step will be tracked during the active order(order acception, messaging, location of driver, start of ride, estimated time till final destination, end of ride and rating). Every step will be visible in application.
6. Ratings. Clients are able to rate the drivers based on certain categories (clean interior, careful driving, politeness and etc.). Ratings are seen by clients when they enter profile of driver.

Admin

1. Admin is able to control every step of clients and drivers. Data, actions, history is his duty. An account for one admin will be created only where he can manage everything later on.

Services

1. Support. In case of emergencies or issues with orders, active AI chat will be in charge for messaging with clients. AI will notify active admins about cases and full chat will be seen by him.

Development stages:

Planning (expected deadlines, release week/date) -> Requirements analysis (full system design, architecture of functionalities in graph view) -> Design (mobile design for IOS and Android, web design for admin's page) -> Coding (page layout - frontend, backend development, service raise, and final integration) -> Testing (Devops) -> Deployment (domain connection and server installation) -> MVP release(Maintenance)

Development requirements:

Full Team of Developers:

1 Frontend Developer
2 Backend developer

3 UI/UX and Graphic designer (one person)
4 Service and AI feature developer
5 Flutter developer

Technical tools:
domains (one), deployment charge for systems (IOS and Android), server
